1 Prologue

Summary:

• This course will focus on planning

• Variables:

- State: $\mathbf{x}(t)$

- Action(s): $\mathbf{u}(t)$

- Measurement: $\mathbf{y}_k^{(i)}$

– Context: $\mathbf{z}_k^{(i)}$

– Old Context: $\mathbf{z}_{k-1}^{(i)}$

- Plan: $\mathbf{p}_k^{(i)}$ - (i): Ith agent

• Conversion to DT is necessary because robots are digitalized system and then converted back to CT for execution.

Setup of Planning Problems 1.1

Summary: In a planning problem, it is assumed that:

- ullet the environment is representable using a discrete set of states, ${\mathcal S}$
- for each state, $s \in \mathcal{S}$, each agent, i, has a discrete set of actions, $\mathcal{A}_i(s)$, with $\mathcal{A}(s) := \times_i \mathcal{A}_i(s)$ (joint action set)
- a move is any tuple, (s, a), where $s \in \mathcal{S}$ and $a \in \mathcal{A}(s)$
- a transition is any 3-tuple, (s, a, s'), where $s, s' \in \mathcal{S}$ and $a \in \mathcal{A}(s)$
 - the transition resulting from a move may be deterministic/stochastic
- $\operatorname{rwd}_i(s, a, s')$ is agent i's reward for the transition, (s, a, s')
- a path is any sequence of transitions of the form

$$p = \langle (s^{(0)}, a^{(1)}, s^{(1)}), (s^{(1)}, a^{(2)}, s^{(2)}), \dots \rangle$$

• each agent wants to realize a path that maximizes its own reward

Warning: A(s) is the joint action set of all agents at state s.

1.2 Components of a Robotic System

Summary:

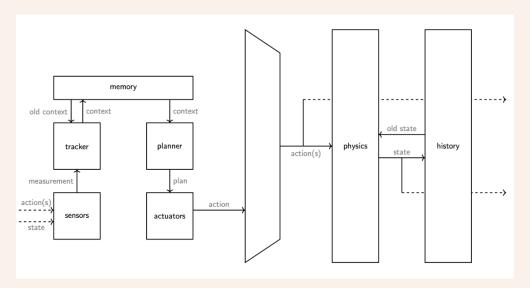

Figure 1: Components of a Robotic System (Words)

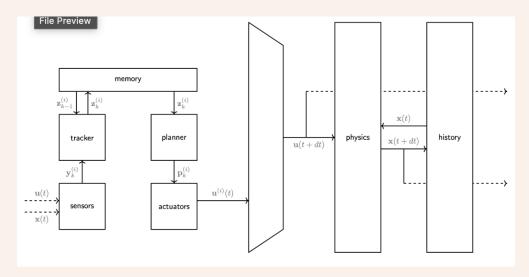

Figure 2: Components of a Robotic System (Math)

1.2.1 Overview (Robots, the Environment)

Definition:

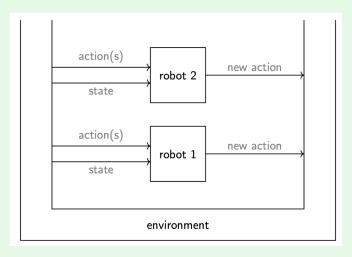

Figure 3: Overview (Robots, the Environment)

Notes:

 \bullet Environment \to previous actions + current state \to robot \to new action \to environment

1.2.2 Robot (Sensors, Actuators, the Brain)

Definition:

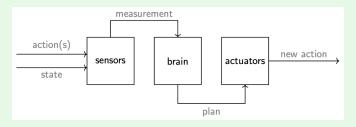

Figure 4: Robot (Sensors, Actuators, the Brain)

Notes:

- \bullet Measurements can be noisy and inaccurate if not a perfect sensor.
- Measurements go into the brain which can create a plan.

1.2.3 Brain (Tracker, Planner, Memory)

Definition:

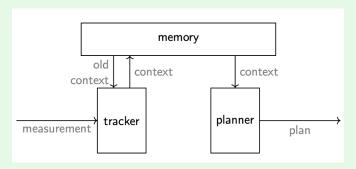

Figure 5: Brain (Tracker, Planner, Memory)

Notes:

- The tracker takes in the measurements and old context and updates the context.
- The planner takes in the context and creates a plan.
- The memory stores the context.

1.2.4 Environment (Physics, State)

Definition:

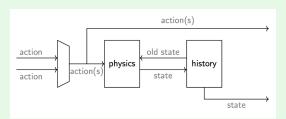

Figure 6: Environment (Physics, State)

1.3 Equations of a Robotic System

1.3.1 Sensing

Definition: Take a measurement:

$$\mathbf{y}^{(i)}(t) = \operatorname{sns}^{(i)}(\mathbf{x}(t), \mathbf{u}(t), t)$$

Convert the measurement into a discrete-time signal using a sampling period of $T^{(i)}$:

$$\mathbf{y}_k^{(i)} = \mathrm{dt}(\mathbf{y}^{(i)}(t), t, T^{(i)})$$

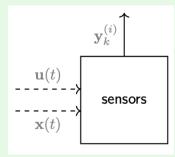

Figure 7: Sensing

1.3.2 Tracking

Definition: Track (update) the context:

$$\mathbf{z}_k^{(i)} = \operatorname{trk}^{(i)} \left(\mathbf{z}_{k-1}^{(i)}, \mathbf{y}_k^{(i)}, k \right)$$

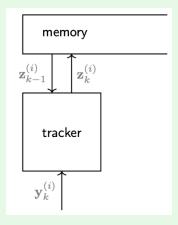

Figure 8: Tracking

1.3.3 Planning

Definition: Make a plan:

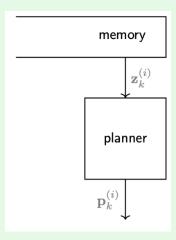

Figure 9: Planning

1.3.4 Acting

Definition: Convert the plan into a continuous-time signal using a sampling period of $T^{(i)}$:

$$\mathbf{p}(t) = \operatorname{ct}(\mathbf{p}_k^{(i)}, t, T^{(i)})$$

Execute the plan:

$$\mathbf{u}^{(i)}(t) = \cot^{(i)}(\mathbf{p}^{(i)}(t), t)$$

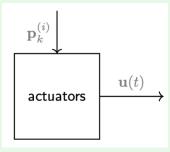

Figure 10: Acting

1.3.5 Simulating

Definition: Simulate the environment's response:

$$\dot{\mathbf{x}}(t) = \text{phy}(\mathbf{x}(t), \mathbf{u}(t), t)$$

Figure 11: Simulating

2 Search Algorithms

Alg.	Halting	Sound	Complete	Optimal	Time	Space
		Un	informed Search Alg	orithms		
BFS	$d < \infty$, non-NULL	always	always	constant cst	b^{l^*}	b^{l^*+1}
• Exp	plores the least-recently	expanded	open node first.			
DFS	$d < \infty$	always	$d < \infty$	never	b^d	bd
• Exp	plores the most-recently	expanded	l open node first.			
IDDFS	always	always	always	constant cst	b^{l^*}	bl^*
• San	ne as DFS but with itera	ative deep	pening.			
CFS	$d < \infty$, non-NULL	yes	$\epsilon > 0$	$\epsilon > 0$	$b^{c^*/\epsilon}$	$b^{c^*/\epsilon+1}$
• Exp	plores the cheapest open	node firs	t.			
		Iı	nformed Search Algor	rithms		
	$d < \infty$	never	never	never		-
HFS	$a < \infty$					
	$a < \infty$ blores the node with the	smallest	hur-value first.			
	plores the node with the			hur admissible, $\epsilon > 0$	$O\left(b^{c^*/\epsilon}\right)$	$O\left(b^{c^*/\epsilon+1}\right)$
• Exp	plores the node with the	always	hur admissible, $\epsilon > 0$	hur admissible, $\epsilon > 0$	$O\left(b^{c^*/\epsilon}\right)$	$O\left(b^{c^*/\epsilon+1}\right)$

2.1 Setup

Definition: In a search problem, it is assumed that:

- There is only one agent (us).
- For each state, $s \in S$, we have a discrete set of actions, $\mathcal{A}(s)$.
- The transition resulting from a move, (s, a), is deterministic; the resulting state is tr(s, a).
- cst(s, a, tr(s, a)) is our cost for the transition, (s, a, tr(s, a)).
- We want to realize a path that minimizes our cost.

A search problem may have no solutions, in which case, we define the solution as NULL.

2.2 Search Graphs

Definition: In a search graph (a graph representing a search problem):

- S is defined by the vertices.
- \mathcal{G} is a subset of the vertices.
- $s^{(0)}$ is some vertex.
- $tr(\cdot, \cdot)$ and \mathcal{T} are defined by the edges.
- $cst(\cdot,\cdot,\cdot)$ is defined by the edge weights.

2.3 Path Trees

Definition: A search algorithm explores a tree of possible paths.

- In such a tree, each node represents the path from the root to itself.
 - The node may also include other info (such as the path's origin, cost, etc).

2.4 Search Algorithms

Definition: All search algorithms follow the template below:

```
 \begin{tabular}{ll} $\mathbb{D} \leftarrow \{(\langle \rangle, 0)\} \\ $\mathbb{D} \in \mathbb{C} \times \mathbb{C} \times
```

 \bullet $\langle \rangle$ is the empty path, and 0 is the cost of the empty path.

```
procedure SEARCH(\mathcal{O})

if \mathcal{O} = \emptyset then

return NULL

n \leftarrow \mathsf{REMOVE}(\mathcal{O})

if \mathsf{DST}(n) \in \mathcal{G} then

return n

for n' \in \mathsf{CHL}(n) do

\mathcal{O} \leftarrow \mathcal{O} \cup \{n'\}

SEARCH(\mathcal{O})

procedure SEARCH(\mathcal{O})

\downarrow the search algorithm failed to find a path to a goal by "explore" a node n

\downarrow the search algorithm found a path to a goal by "expand" n and "export" its children search n
```

- Explore: Remove a node from the open set.
- Exapnd: Generate the children of the node.
- Export: Add the children to the open set.

Warning: The key difference is in the order that $Remove(\cdot)$ removes nodes.

2.4.1 Characteristics of a Search Algorithm

Definition: We want to choose REMOVE(·) so that the algorithm exhibits the following characteristics:

Characteristic	Description
Halting	Terminates after finitely many nodes explored
Sound	Returned (possibly NULL) solution is correct
Complete	Halting and sound when a non-NULL solution exists
Optimal	Returns an optimal solution when multiple exist
Time Efficient	Minimizes the nodes explored /expanded/exported
Space Efficient	Minimizes the nodes simultaneously open

• Will be using explored for time efficiency.

The characteristics of the algorithm also depend on several properties of the path tree over which it searches. These properties include:

- Branching factor: b ($b < \infty$), the maximum number of children a node can have.
- Depth: d, the length of the longest path.
- Length of the shortest solution: l^*

- Cost of the cheapest solution: c^*
- Cost of the cheapest edge: ϵ

We want to choose REMOVE(·) so that the algorithm exhibits the aforementioned characteristics for as many path trees as possible.

2.5 Modifications to Search Algorithms

2.5.1 Depth-Limiting

Definition: Depth limit of d_{max} to any search algorithm by modifying SEARCH(·) as follows:

```
procedure SEARCHDL(\mathcal{O}, d_{\max}):

if \mathcal{O} = \emptyset then

return NULL

n \leftarrow \text{REMOVE}(\mathcal{O})

if \text{dst}(n) \in \mathcal{G} then

return n

for n' \in \text{chl}(n) do

if \text{len}(n') \leq d_{\max} then

\mathcal{O} \leftarrow \mathcal{O} \cup \{n'\}

SEARCHDL(\mathcal{O}, d_{\max})

b the search algorithm failed to find a path to a goal \mathcal{O} "explore" a node, n

\mathcal{O} \leftarrow \mathcal{O} \cup \{n'\}

SEARCHDL(\mathcal{O}, d_{\max})
```

2.5.2 Iterative Deepening

Definition: Iteratively increase the depth-limit, d_{max} , to any search algorithm w/ depth-limiting, by placing SEARCHDL(·) in a wrapper, SEARCHID(·):

```
procedure SEARCHID(): n \leftarrow \text{NULL} \\ d_{\text{max}} \leftarrow 0 \\ \text{bwhile a solution has not been found, reset the open set, run the search algorithm, then increase the depth-limit while <math>n = \text{NULL do} \mathcal{O} \leftarrow \{(\langle \rangle, 0)\} \\ n \leftarrow \text{SEARCHDL}(\mathcal{O}, d_{\text{max}}) \\ d_{\text{max}} \leftarrow d_{\text{max}} + 1 \\ \text{return } n
```

Warning: Increasing d_{max} can be done in different ways.

2.5.3 Cost-Limiting

Definition: Cost limit of c_{max} to any search algorithm by modifying SEARCH(·) as follows:

```
procedure SEARCHCL(\mathcal{O}, c_{\max}):

if \mathcal{O} = \emptyset then

return NULL

n \leftarrow \text{REMOVE}(\mathcal{O})

if \text{dst}(n) \in \mathcal{G} then

return n

for n' \in \text{chl}(n) do

if \text{cst}(n') \leq c_{\max} then

\mathcal{O} \leftarrow \mathcal{O} \cup \{n'\}

SEARCHCL(\mathcal{O}, c_{\max})

be the search algorithm failed to find a path to a goal

be "explore" a node, n

be the search algorithm found a path to a goal

be "expand" n and "export" its children be unless the child is too expensive
```

2.5.4 Iterative-Inflating

Definition: Iteratively increase the cost limit, c_{max} , to any search algorithm with cost-limiting, by placing SEARCHCL(·) in a wrapper, SEARCHII(·):

```
procedure SEARCHII(): n \leftarrow \text{NULL}
c_{\text{max}} \leftarrow 0
\text{while a solution has not been found, reset the open set, run the search algorithm, then increase the cost-limit while <math>n = \text{NULL do}
\mathcal{O} \leftarrow \{(\langle \rangle, 0)\}
n \leftarrow \text{SEARCHCL}(\mathcal{O}, c_{\text{max}})
c_{\text{max}} \leftarrow c_{\text{max}} + \epsilon
\text{return } n
```

Warning: Increasing c_{max} can be done in different ways.

2.5.5 Intra-Path Cycle Checking

Definition: Do not expand a path if it is cyclic. Modify SEARCH(·) as follows:

```
procedure SEARCH(\mathcal{O}):

if \mathcal{O} = \emptyset then

return NULL

n \leftarrow \text{REMOVE}(\mathcal{O})

if \text{dst}(n) \in \mathcal{G} then

return n

for n' \in \text{chl}(n) do

if not CYCLIC(n') then

\mathcal{O} \leftarrow \mathcal{O} \cup \{n'\}

SEARCH(\mathcal{O})
```

• Optimately of an algorithm is preserved provided $\epsilon > 0$.

2.5.6 Inter-Path Cycle Checking

```
Definition: We modify SEARCH(\cdot) as follows:
```

```
procedure SEARCH(\mathcal{O}, \mathcal{C}):

if \mathcal{O} = \emptyset then

return NULL

n \leftarrow \text{REMOVE}(\mathcal{O})

\mathcal{C} \leftarrow \mathcal{C} \cup \{n\}

if dst(n) \in \mathcal{G} then

return n

for n' \in \text{chl}(n) do

if n' \notin \mathcal{C} then

\mathcal{O} \leftarrow \mathcal{O} \cup \{n'\}

SEARCH(\mathcal{O}, \mathcal{C})
```

and then call the algorithm as follows:

```
 \begin{array}{c} 1\\ \mathcal{O} \leftarrow \{(\langle\rangle,0)\}\\ \mathcal{C} \leftarrow \emptyset \\ \text{SEARCH}(\mathcal{O},\ \mathcal{C}) \end{array} \hspace{0.5cm} \triangleright \text{ initialize a set of closed vertices}
```

2.6 Informed Search Algorithms

2.6.1 Estimated Cost

Definition: $ecst(\cdot)$, to estimate the total cost to a goal given a path, p, based on the following:

- Cost of path p: cst(p)
- Estimate of the extra cost needed to get to a goal from dst(p): hur : $S \to \mathbb{R}_+$
 - hur(s) estimates the cost to get to \mathcal{G} from s and hur(p) means hur(dst(p)).

Example: Some common choices for $ecst(\cdot)$ include:

- 1. ecst(p) = hur(p); called nearest-first search (NFS)
- 2. $\operatorname{ecst}(p) = \operatorname{cst}(p) + \operatorname{hur}(p)$; called A* (A-star)

2.7 Characteristics of an Informed Search Algorithm

Definition:

- 1. Heuristic: $hur(\cdot)$
- 2. Cost estimation: $ecst(\cdot)$
- 2.7.1 Heuristics
- 2.7.2 Designing Heuristics via Problem Relaxation
- 2.7.3 Combining Heuristics
- 2.8 Anytime Search Algorithms
- 2.9 Formulating a Search Problem

2.10 Canonical Examples

Process: How to setup a search problem?

- 1. Givne a search graph, we need to define the following:
 - S: set of vertices
 - \mathcal{G} : goal states (subset of \mathcal{S})
 - $s^{(0)}$: initial state
 - \mathcal{T} : set of edges (defined by $\operatorname{tr}(\cdot,\cdot)$)
 - $-\operatorname{tr}(\cdot,\cdot)$: transition function
 - $cst(\cdot,\cdot,\cdot)$: cost function (defined by edge weights)

Example:

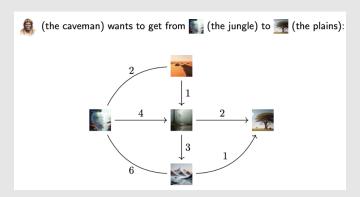

Figure 12

Figure 13

Example:

His energy consumption for a given step depends on the terrain transition.

Figure 14

Figure 15

- $S = \{0, \dots, 4\}^2$ $G = \left\{ \begin{bmatrix} 1 \\ 4 \end{bmatrix} \right\}$ $s^{(0)} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$

Process: How to setup a path tree? 1. Start at $s^{(0)}$

- 2. Choose a path until you reach a goal state.
- 3. Repeat until you have found all paths (probably infinite).

Example: 6 Figure 16 Figure 17

Process: When to use each algorithm?

- 1. Find properties needed for the problem and match them to the characteristics of the algorithm.
- 2. Choose the algorithm that best matches the properties.
 - BFS:
 - DFS:
 - IDDFS:
 - CFS:
 - A*:

Example:

Example:

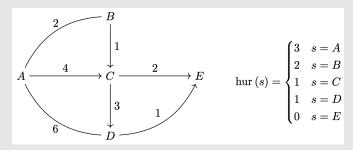

Figure 18

Process: BFS

- 1. Start at s_0
- 2. Expand all neighboring nodes of the current node and add them to the open set (queue).
- 3. Remove the current node from the open set and mark it as visited.
- 4. Repeat steps 2 and 3 until the goal state is reached or the open set is empty.

Example: BFS

Path	Open Set
$A \\ AB \\ ABC \\ ABCD \\ ABCDE$	$\{A\}$ $\{B, C, D\}$ $\{C, D, E\}$ $\{D, E\}$ $\{E\}$

Process: DFS

- 1. Start at s_0 (initial state).
- 2. Push the initial node onto the stack.
- 3. Pop a node from the stack and expand it.
- 4. Push all unvisited children of the current node onto the stack.
- 5. Repeat steps 3 and 4 until the goal state is reached or the stack is empty.

Example: DFS

Path	Open Set
	$\{A\}$
A	$\{B,C,D\}$
AD	$\{B,C,E\}$
ADE	$\{C,B\}$

Process: IDDFS

- 1. Start with a depth limit of 0.
- 2. Perform Depth-First Search (DFS) up to the current depth limit.
- 3. If the goal state is not reached and there are unexplored nodes, increment the depth limit and repeat step 2.
- 4. Continue until the goal state is found or all nodes are explored.

Example: IDDFS

Depth	Path	Open Set
0		$\{A\}$
0	A	{}
1	\overline{A}	$\{B,C,D\}$
1	AB	$\{C,D\}$
1	AC	$\{D\}$
1	AD	{}
2	AD	$\{E\}$
2	ADE	{}

Process: CFS

- 1. Start at s_0 (initial state).
- 2. Initialize the open set (priority queue) with the initial state and its cost.
- 3. Remove the node with the lowest cost from the open set.
- 4. Expand the node and add all unvisited neighbors to the open set with their cumulative costs.
- 5. Repeat steps 3 and 4 until the goal state is reached or the open set is empty.

Example: CFS

Path	Open Set
	$\{A \mid 0\}$
A	$\{AB \mid 2, AC \mid 4, AD \mid 6\}$
AB	$\{AC \mid 4, AD \mid 6, ABC \mid 3\}$
ABC	$\{AC \mid 4, AD \mid 6, ABCE \mid 5, ABCD \mid 6\}$
ABCE	$\{AC \mid 4, AD \mid 6, ABCD \mid 6\}$

Process: HFS

- 1. Start at s_0 (initial state).
- 2. Initialize the open set with the initial state and its heuristic value.
- 3. Remove the node with the lowest heuristic value from the open set.
- 4. Expand the node and add all unvisited neighbors to the open set with their heuristic values.
- 5. Repeat steps 3 and 4 until the goal state is reached or the open set is empty.

Example: HFS

Path	Open Set		
4	$\{A \mid 3\}$		
$A \\ AC$	$\{AB \mid 2, AC \mid 1, AD \mid 1\}$ $\{AB \mid 2, AD \mid 1, ACE \mid 0\}$		
ACE	$\{AB \mid 2, AD \mid 1\}$		

Process: A*

- 1. Start at s_0
- 2. Choose path in open set that gives lowest $\operatorname{esct}(p) = \operatorname{cst}(p) + \operatorname{hur}(p)$.
- 3. Expand and export children onto open set.
- 4. Repeat until goal state is reached.

Example: A^*

Path	Open Set
	$\{A \mid 3\}$
A	$\{AB \mid 2+2, AC \mid 4+1, AD \mid 6+1\}$
AB	$\{AC \mid 5, AD \mid 7, ABC \mid 3+1, ABA \text{ intra}\}$
ABC	$\{AC \mid 5, AD \mid 7, ABCD \mid 6+1, ABCE \mid 5+0\}$
AC	$\{AD \mid 7, \ ABCD \mid 7, \ ABCE \mid 5, \ ACD \mid 7+1, \ ACE \mid 6+0\}$
ABCE	$\{AD \mid 7, \ ABCD \mid 7, \ ACD \mid 8, \ ACE \mid 6\}$

Example: IIA*

Example: WA*

Process: How to Figure Out Soln. w/o Performing Search Algorithm? 1.

Example:

Process: How to Prove Consistent/Admissible Given a Search Graph?

Admissible:

- 1. Given hur(s) and search graph with cst(s, a, tr(s, a)) or rwd(s, a, tr(s, a)). If consistent, then it is admissible.
- 2. Check $\forall s \in \mathcal{G}$, hur(s) = 0. If not, then it is not admissible.
- 3. For each $s \in \mathcal{S}$, calculate hur*(s) (i.e. actual cost of optimal soln.) using the search graph.
 - (a) Start at s and choose path that gives the lowest cost or highest reward to $s \in \mathcal{G}$.
- 4. Check if $\operatorname{hur}(s) \leq \operatorname{hur}^*(s) \ \forall s \in \mathcal{S}$. If not, then it is not admissible.
- 5. Repeat $\forall s \in \mathcal{S}$.
- 6. If all are true, then it is admissible.

Consistent:

- 1. Given hur(s) and search graph with cst(s, a, tr(s, a)) or rwd(s, a, tr(s, a)).
- 2. Check $\forall s \in \mathcal{G}$, hur(s) = 0. If not, then it is not consistent.
- 3. For each $s \in \mathcal{S}$, calculate hur(s) hur(tr(s, a)).
 - (a) check if it is $\leq \operatorname{cst}(s, a, \operatorname{tr}(s, a))$ or $\geq \operatorname{rwd}(s, a, \operatorname{tr}(s, a))$. If not, then it is not consistent.
 - (b) Repeat $\forall a \in \mathcal{A}(s)$
- 4. Repeat $\forall s \in \mathcal{S}$.
- 5. If all are true, then it is consistent.

Warning: Be careful of bidirectional edges be for consistency you need compute the cost of the heuristic edge in both directions.

Example:

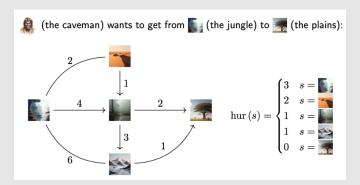

Figure 19: Jungle $(s^{(0)})$, Desert, Swamp, Mountain, Plains (Goal)

Admissible:

- 1. s =Plains: hur(Plains) = 0
- 2. $s = Jungle: hur(Jungle) = 3 \le hur^*(Jungle) = 2 + 1 + 2 = 5$
- 3. s =**Desert:** $hur(Desert) = 2 < hur^*(Desert) = 1 + 2$
- 4. $s = \mathbf{Swamp}$: $\operatorname{hur}(\operatorname{Swamp}) = 1 \le \operatorname{hur}^*(\operatorname{Swamp}) = 2$
- 5. $s = Mountain: hur(Mountain) = 1 \le hur^*(Mountain) = 1$
- 6. Therefore, it is admissible.

Consistent:

- 1. s =Plains: hur(Plains) = 0
- 2. s =Jungle:
 - (a) $hur(Jungle) hur(Desert) = 3 2 = 1 \le cst(Jungle, \cdot, Desert) = 2$
 - (b) $hur(Jungle) hur(Swamp) = 3 1 = 2 \le cst(Jungle, \cdot, Swamp) = 4$
 - (c) $hur(Jungle) hur(Mountain) = 3 1 = 2 \le cst(Jungle, \cdot, Mountain) = 6$
- 3. s = Deserts
 - (a) $hur(Desert) hur(Jungle) = 2 3 = -1 \le cst(Desert, \cdot, Jungle) = 2$
 - (b) $hur(Desert) hur(Swamp) = 2 1 = 1 \le cst(Desert, \cdot, Swamp) = 1$
- 4. $s = \mathbf{Swamp}$:
 - (a) $hur(Swamp) hur(Mountain) = 1 1 = 0 \le cst(Swamp, \cdot, Mountain) = 3$

- (b) $hur(Swamp) hur(Plains) = 1 0 = 1 \le cst(Swamp, \cdot, Plains) = 2$
- 5. s = Mountain:
 - (a) $hur(Mountain) hur(Jungle) = 1 3 = -2 \le cst(Mountain, \cdot, Desert) = 6$
 - (b) $\operatorname{hur}(\operatorname{Mountain}) \operatorname{hur}(\operatorname{Plains}) = 1 0 = 1 \le \operatorname{cst}(\operatorname{Mountain}, \cdot, \operatorname{Plains}) = 1$
- 6. Therefore, it is consistent.

Process: How to Design Heuristic via Problem Relaxation?

- $1.\,$ Make an assumption to simplify the problem as a relaxed problem.
- 2. Find the cost of the optimal solution of the relaxed problem, $\operatorname{cst}_{\operatorname{rel}}(s)$.
- 3. HOW TO FIND THE COST OF THE OPTIMAL SOLUTION?

Example:

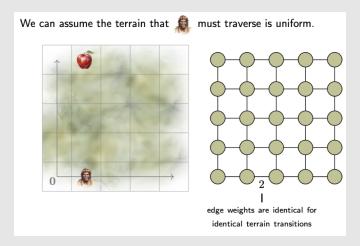

Figure 20

3 Constraint Satisfaction Problems

3.1 Setup of CSP

Definition: A constraint satisfaction problem (CSP) consists of:

- a set of variables, \mathcal{V} , where the domain of $V \in \mathcal{V}$ is dom(V)
- a set of **constraints**, C, where the scope of $C \in C$ is $scp(C) \subseteq V$

3.2 Assignment

Definition: An **assignment** is a set of pairs, $\{(V,v)\}_{V\in\tilde{\mathcal{V}}}$, where $v\in \text{dom}(V)$, and $\tilde{\mathcal{V}}\subseteq\mathcal{V}$. It is **complete** if $\tilde{\mathcal{V}}=\mathcal{V}$, and **partial** otherwise.

3.3 Consistent

3.3.1 Complete Assignment

Definition: A complete assignment, A, is **consistent** if it satisfies every constraint \mathcal{C} with $scp(\mathcal{C}) \subseteq \tilde{\mathcal{V}}$.

Warning: A solution to a CSP is any complete and consistent assignment.

3.3.2 Partial Assignment

Definition: A (possibly partial) assignment, $\{(V, v)\}_{V \in \tilde{\mathcal{V}}}$, is **consistent** if it satisfies every constraint, $C \in \mathcal{C}$ such that $\text{scp}(C) \subseteq \tilde{\mathcal{V}}$.

3.4 k-Consistent

Definition: A CSP is k-consistent if for any consistent assignment of k-1 variables, $\{(V,v)\}_{V\in\tilde{\mathcal{V}}}$, and any k^{th} variable, V', there is a value, $v'\in \text{dom}(V')$, so the assignment, $\{(V,v)\}_{V\in\tilde{\mathcal{V}}}\cup \{(V',v')\}$ is consistent.

3.4.1 Edge/Arc Consistent

Definition: 2-consistent.

3.5 Setup of CSP

Example:

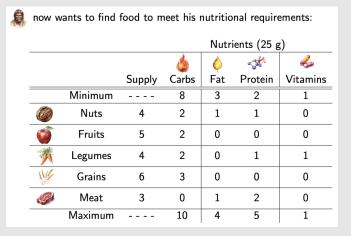

Figure 21

For our example, the variables could be:

Figure 22

Figure 23

Process: How to build a hyper-graph?

1. Circle the variables that appear in constraint $C_i \, \forall i$.

Example:

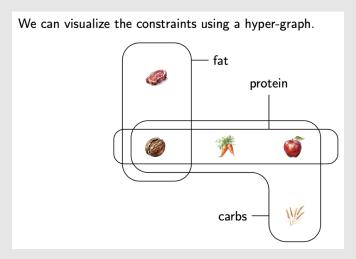

Figure 24

Process: How to build a path tree?

Example:

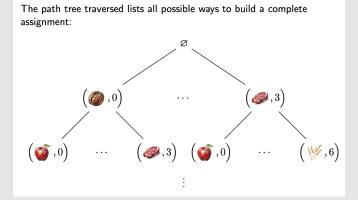

Figure 25

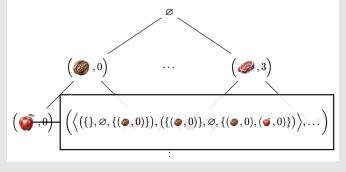

Figure 26

Process: How to determine a solution to a CSP?

1.

Example:

$$\left\{ \left(\textcircled{0},2\right) ,\left(\textcircled{0},1\right) ,\left(\textcircled{7},1\right) ,\left(\textcircled{1},0\right) ,\left(\textcircled{2},1\right) \right\}$$

Figure 27

Process: How to check k-Consistency?

- 1. Given \mathcal{V} w/ dom $(V) = \{v_1, \dots, v_{|\text{dom}(V)|}\}\ \forall V \in \mathcal{V}$ and \mathcal{C} w/ scp $(C) = \{V_1, \dots, V_{|\text{scp}(C)|}\}\ \forall C \in \mathcal{C}$.
- 2. Remove all constraints that have k+1 or more variables.
- 3. For each $C \in \mathcal{C}$, do the following:
 - (a) For each $V \in \operatorname{scp}(C)$, do the following:
 - i. For each $v \in \text{dom}(V)$, do the following:
 - Fix V to v.
 - For the other $V \in \operatorname{scp}(C)$, check if the constraint is satisfied by trying all combinations (need only one).
 - **Key:** If there is one combination that doesn't satisfy the constraint, then the CSP is not k-consistent.
- 4. If all constraints are satisfied, then the CSP is k-consistent.

Process: How to Enforce k-Consistency?

- 1. Given \mathcal{V} w/ dom $(V) = \{v_1, \dots, v_{|\text{dom}(V)|}\}\ \forall V \in \mathcal{V}$ and \mathcal{C} w/ scp $(C) = \{V_1, \dots, V_{|\text{scp}(C)|}\}\ \forall C \in \mathcal{C}$.
- 2. Remove all constraints that have k+1 or more variables.
- 3. **Pre-pruning:** For each remaining $C \in \mathcal{C}$, do the following:
 - (a) For each $V \in \operatorname{scp}(C)$, do the following:
 - i. For each $v \in \text{dom}(V)$, do the following:
 - Fix V to v.
 - For the other $V \in scp(C)$, check if the constraint is satisfied by trying all combinations (need only one).
 - **Key:** If the constraint is not satisfied, then remove the value from dom(V).
- 4. If you had to remove any values from dom(V), then check with the other constraints.
- 5. **Pruning:** Every constraint is satisfied.

Example:

•
$$V = \{ \begin{subarray}{ll} & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\$$

Figure 28

• dom
$$(\)$$
 = $\{1, 2, 3\}$
• dom $(\)$ = $\{2, 3, 4\}$
• dom $(\)$ = $\{1, 2, 3\}$

Figure 29: Pre-pruning. Since only one constraint, it is also pruning.

Example: Different ways to formulate the CSP problem.

- How can you formulate the CSP problem in a different way? Can I get a specific example?
 - The domain could be set to everything, then set the constraints later.
- What is the constraint graph showing? Grouping the variables
- How do you check consistency in a CSP?
- Why can you use any search algorithm when you formulate this as a search problem?
- What does a node contain? A node contans a path.
 - How does that match the example on slide 10. It does.
- Why is formulalting a CSP problem as a search problem a bad idea? B/c you have to search through all possible combinations, but if you find a constraint then you can prune the search space.
 - A lot easier to see if there is a solution or not. But in a search problem, you see if there's a solution and how to get to it.

Learning Problems

4 PAC Learning

Definition: Assume that there is some (unknown) relationship,

$$f: \mathcal{X} \to \mathcal{Y} \text{ s.t. } x \mapsto_f y$$

- X: Input Space
- \mathcal{Y} : Output Space (i.e. Information we desire about input)

Find $h: \mathcal{X} \to \mathcal{Y}$ (hypothesis) s.t. $h \approx f$, given some data about f:

$$\mathcal{D} = \left\{ \left(x^{(i)}, y_i \right), x^{(i)} \in \mathcal{X}, y_i = f\left(x^{(i)} \right) \in \mathcal{Y}, i = 1 \dots N \right\}$$

- $\operatorname{in}(\mathcal{D}) = \{x \text{ s.t. } (x, y) \in \mathcal{D}\}$
- out(\mathcal{D}) = {y s.t. $(x, y) \in \mathcal{D}$ }

4.1 Classification vs. Regression Problems

Definition:

- Classification Problems: $\mathcal{X} \subseteq \mathbb{R}^M$ and $\mathcal{Y} \subseteq \mathbb{N}$
- Regression Problems: $\mathcal{X} \subseteq \mathbb{R}^M$ and $\mathcal{Y} \subseteq \mathbb{R}$

4.2 Feature Spaces

Definition: It is often easier to learn relationships from high-level features (instead of the raw input).

4.3 Feasibility of Learning

Motivation: More than one function (hypothesis) may be consistent with the data.

Notes: So it may appear that finding the correct one should be impossible.

4.3.1 Probably Approximately Correct (PAC) Estimations

Example: Take N i.i.d. samples (i.e. take out a ball from an urn, record its color, and put it back in).

• $\nu \to \mu$ (empirical distribution \to true distribution) as $N \to \infty$

4.3.2 Hoeffding's Inequality

Definition: Let μ denote the probability of an event, and ν denote its relative frequency in a sample size N. Then, for any $\epsilon > 0$,

$$P(|\nu - \mu| > \epsilon) \le 2e^{-2\epsilon^2 N} \tag{1}$$

- ν : Relative frequency in the sample (known)
- μ : Probability of drawing a blue ball (unknown)
- $N \to \infty$: $\nu \to \mu$
- ϵ : How close we want ν to be to μ
- $\epsilon \to 0$: Probability will be 1
- $\epsilon \to \infty$: $\nu \to \mu$
- $\mu \approx \nu$: μ is probably approximately equal to nu.

Warning: We can approximate the true distribution with high probability by taking a large enough sample size, NOT guaranteeing that we can find the true distribution.

• Don't need to know where this theorem comes from.

Consider determining the class of a randomly chosen target point. If we ask a K-ary question about the points in \mathcal{D}

4.3.3 PAC Learning

5 Decision Trees

5.1 Decision Trees

Motivation: A simple model used for classification problems.

We want to find the minimum # of condition vertices (or questions) needed to "sufficiently discriminate" (identify the class of every point in \mathcal{D}).

5.1.1 Structure

Definition: Each vertex in a decision tree is either:

- 1. A **condition vertex**: a vertex that sorts points based on a question.
- 2. A decision vertex: a vertex that assigns all points a specific class.

Warning:

- More condition vertices improve discrimination.
- Less condition vertices improve generalization.

5.2 Building a Decision Tree: The General Case

Motivation: Suppose points do not necessarily belong to a unique class.

In the context of decision trees:

- X is the class of a randomly chosen target point.
- Y is the answer to a K-ary question for X.

Maximize IG(X|Y) (i.e. choose the question to maximize the information gained).

5.2.1 Entropy, Conditional Entropy, and Information Gain

Definition: The **entropy** of a random variable X (in K-its) is defined as

$$H(X) = -\sum_{\forall x \in X} p_X(x) \log_K(p_X(x)).$$

The **conditional entropy** of a random variable, X, given a random variable Y, is

$$H(X|Y) = -\sum_{\forall y \in Y} \sum_{\forall x \in X} p_{X|Y}(x|y) \log_K(p_{X|Y}(x|y)).$$

The **information gain** from Y is:

$$IG(X|Y) = H(X) - H(X|Y).$$

Warning:

• There are ∞ many potential questions, but there are only finite many ways to split the dataset.

Process:

- 1. Calculate H(X) (i.e. entropy before the split).
- 2. Calculate H(X|Y) (i.e. entropy after the split).
 - (a) Calculate entropy for each subset of X based on the question, Y.
 - (b) Calculate the weighted average of the entropies.
- 3. Calculate IG(X|Y) = H(X) H(X|Y).

Example:

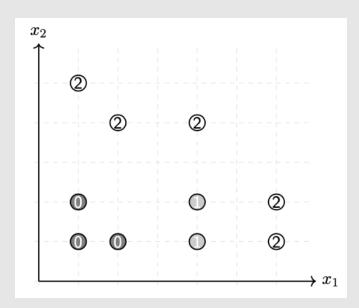

Figure 30

Example: 2-Ary Question

- 1. **Given:** $X = \{0, 1, 2\}, Y = \begin{cases} 1, & \text{if } x_1 \le 3 \\ 0, & \text{if } x_1 > 3 \end{cases}$ (Yes)
- 2. **Problem:** IG(X|Y) = ?
- 3. Solution:
 - (a) Entropy before the split: $H(X) = \frac{3}{10} \log_2 \left(\frac{10}{3}\right) + \frac{2}{10} \log_2 \left(\frac{10}{2}\right) + \frac{5}{10} \log_2 \left(\frac{10}{5}\right)$
 - (b) Entropy after the split:

i.
$$H(X_{\text{left}}) = \frac{3}{5} \log_2 \left(\frac{5}{3}\right) + \frac{2}{5} \log_2 \left(\frac{5}{2}\right)$$

ii.
$$H(X_{\text{right}}) = \frac{2}{5} \log_2 \left(\frac{5}{2}\right) + \frac{3}{5} \log_2 \left(\frac{5}{3}\right)$$
.

iii. Weighted Avg. Entropy:
$$H(X|Y) = \frac{5}{10}H(X_{\text{left}}) + \frac{5}{10}H(X_{\text{right}})$$

(c) IG(X|Y) = H(X) - H(X|Y)

Example: 2-Ary Question

- 1. **Given:** $X = \{0, 1, 2\}, Y = \begin{cases} 1, & \text{if } x_2 \le 3 \\ 0, & \text{if } x_2 > 3 \end{cases}$ (Yes)
- 2. **Problem:** IG(X|Y) = ?
- 3. Solution:
 - (a) Entropy before the split: $H(X) = \frac{3}{10} \log_2 \left(\frac{10}{3}\right) + \frac{2}{10} \log_2 \left(\frac{10}{2}\right) + \frac{5}{10} \log_2 \left(\frac{10}{5}\right)$
 - (b) Entropy after the split:

$$\begin{split} \text{i. } & H(X_{\text{top}}) = \frac{3}{3} \log_2 \left(\frac{3}{3} \right) \\ & \text{ii. } & H(X_{\text{bottom}}) = \frac{3}{5} \log_2 \left(\frac{5}{3} \right) + \frac{2}{5} \log_2 \left(\frac{5}{2} \right) + \frac{2}{5} \log_2 \left(\frac{5}{2} \right). \\ & \text{iii. Weighted Avg. Entropy: } & H(X|Y) = \frac{3}{10} H(X_{\text{top}}) + \frac{7}{10} H(X_{\text{bottom}}) \\ & \text{(c) } & IG(X|Y) = H(X) - H(X|Y) \end{split}$$

Example: 3-Ary Question

1. Given:
$$X = \{0, 1, 2\}, Y = \begin{cases} 1, & \text{if } x_1 \leq 3 \text{ and } x_2 \leq 3 \\ 2, & \text{if } x_1 \leq 3 \text{ and } x_2 > 3 \\ 3, & \text{if } x_1 > 3 \end{cases}$$

- 2. **Problem:** IG(X|Y) = ?
- 3. Solution:

(a) Entropy before the split:
$$H(X) = \frac{3}{10} \log_2 \left(\frac{10}{3}\right) + \frac{2}{10} \log_2 \left(\frac{10}{2}\right) + \frac{5}{10} \log_2 \left(\frac{10}{5}\right)$$

(b) Entropy after the split:

i.
$$H(X_1) = \frac{3}{3}\log_2\left(\frac{3}{3}\right)$$

ii. $H(X_2) = \frac{2}{2}\log_2\left(\frac{2}{2}\right)$
iii. $H(X_3) = \frac{2}{5}\log_2\left(\frac{5}{2}\right) + \frac{3}{5}\log_2\left(\frac{5}{3}\right)$
iv. $H(X|Y) = \frac{3}{10}H(X_1) + \frac{2}{10}H(X_2) + \frac{5}{10}H(X_3)$
(c) $IG(X|Y) = H(X) - H(X|Y)$

Example: Decision Tree

- 1. **Given:** $X = \{0, 1, 2\}$
- 2. **Problem:** Draw a decision tree using binary conditions of the form, $x_i \leq k$, where $i \in \{1, 2\}$ and $k \in \mathbb{Z}$, that maximizes the information gained at each level.
- 3. Solution:

(a)
