Turn-Taking Multi-Agent Decision Algorithms

1 Turn-Based Games

1.1 Zero-Sum Turn-Based Games

Summary: In a zero-sum turn-based games, we assume that

- Agents and Environment:
 - there are two agents, called the **maximizer** and **minimizer**
 - the environment is always in one of a discrete set of states, \mathcal{S}
 - a subset of the states, $\mathcal{T} \subseteq \mathcal{S}$, are terminal states
 - there is only one decision maker for each non-terminal state, $s \in \mathcal{S} \setminus \mathcal{T}$
 - For each non-terminal state, $s \in \mathcal{S} \setminus \mathcal{T}$, the decision-maker has a discrete set of actions, $\mathcal{A}(s)$
- **Decision Process:** At time-step t, the decision-maker will:
 - **Observe:** Observe the state s_t
 - **Select:** Select an action $a_t \in \mathcal{A}(s_t)$
 - Move: Make the move (s_t, a_t)
- State Transitions:
 - Environment transitions to a deterministic state, s_{t+1} , based on a stationary fn,

$$s_{t+1} = \operatorname{tr}(s_t, a_t)$$

- Once a terminal state is reached (if $s_{t+1} \in \mathcal{T}$), the maximizer obtains a reward for the final transition based on a reward fn, $r(\cdot, \cdot, \cdot)$:

 $r(s_t, a_t, s_{t+1}) = \text{maximizer's reward for reaching state } s_{t+1}$

 $-r(s_t, a_t, s_{t+1}) = \text{minimizer's reward for reaching state } s_{t+1}$

Warning:

- Maximizer is trying to maximize the reward of agent 1
- Minimizer is trying to minimize the reward of agent 1 (i.e. maximize the reward of agent 2)

1.2 α/β Pruning

Motivation: Don't explore the entire game tree by pruning branches that are unreachable under perfect play.

Definition: For each state s:

- α_s : Maximum value at s thus far (initially $-\infty$)
- β_s : Minimum value at s thus far (initially $+\infty$)

1.2.1 α Cuts

Definition: If the maximizer is the turn-taker at s, then α_s increases to the maximum value of s's successors as they are explored, and $\beta_s = \beta_{\text{parent}(s)}$.

• If α_s increases beyond β_s , then s unreachable under perfect play.

1.2.2 β Cuts

Definition: If the **minimizer** is the turn-taker at s, then β_s decreases to the minimum value of s's successors as they are explored, and $\alpha_s = \alpha_{\text{parent}(s)}$.

• If β_s decreases beyond α_s , then s unreachable under perfect play.

1.3 Examples

1.3.1 Zero Sum Turn-Based Games

Example:

- Given: Cavemen is injured from his hunt. He has extra food, but needs medicine.
 - He meets another caveman who is willing to trade.

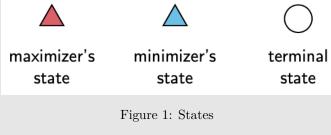

Figure 2: Actions

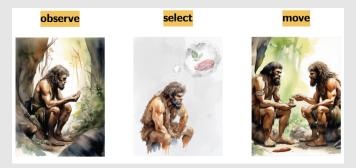

Figure 3: Decision Process

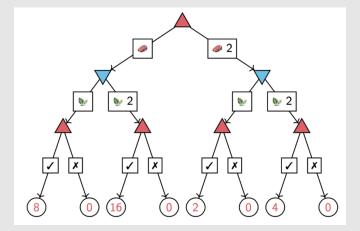

Figure 4: Game Tree

- States
 - * Red triangle: Maximizing agent
 - * Blue triangle: Minimizing agent
 - * White circles with # s: terminal states
- Actions: Square boxes are actions
- Solution: Backtracking through the game tree, we can find the optimal path for the maximizer and minimizer.

ROB311 Hanhee Lee

- Maximizer Turn: LL: Accept to get reward of 8, L: Accept to get reward of 16, R: Accept to get reward of 2, RR: Accept to get reward of 4
- Minimizer Turn: LL: 1 medicine to make maximizer get reward of 8, R: 1 medicine to make maximizer get reward of 2
- Maximizer Turn: 1 food to make maximizer get reward of 8 b/c going right will make maximizer get reward of 2
- Optimal Path: Therefore, the optimal path will be LLL b/c the maximizer will get a reward of 8, while the minimizer will reduce the reward from 16 to 8.
 - * Assume boths agents play optimally, this will be the path taken.

1.3.2 α Cuts

Example:

- Explored 14, 12 and now $\beta_{parent(s)} = \beta_s = 5$, so this will be compared for α_s until $\alpha_s > \beta_s$ b/c then s unreachable under perfect play.
- Iterate:
 - $-\alpha_s = -\infty < \alpha_s' = 2 \rightarrow \alpha_s = 2$, but $\alpha_s = 2 < \beta_s = 5$

 - $-\alpha_s = 2 < \alpha_s' = 4 \rightarrow \alpha_s = 4$, but $\alpha_s = 4 < \beta_s = 5$ $-\alpha_s = 4 < \alpha_s' = 9 \rightarrow \alpha_s = 9$, and $\alpha_s = 9 > \beta_s = 5$, therefore, prune all the other branches that haven't been explored yet in the children of s paths

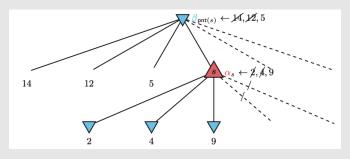

Figure 5

1.3.3 β Cuts

Example:

- Explored 4,6, and now $\alpha_{\text{parent}(s)} = \alpha_s = 7$, so this will be compared for β_s until $\beta_s < \alpha_s$ b/c then s unreachable under perfect play.
- Iterate:
 - $-\beta_s = +\infty > \beta_s' = 9 \rightarrow \beta_s = 9$, but $\beta_s = 9 > \alpha_s = 7$
 - $-\beta_s = 9 > \beta'_s = 8 \to \beta_s = 5$, but $\beta_s = 8 > \alpha_s = 7$
 - $-\beta_s = 8 > \beta_s' = 3 \rightarrow \beta_s = 3$, and $\beta_s = 3 < \alpha_s = 7$, therefore, prune all the other branches that haven't been explored yet in the children of s paths
